

INTRODUCTION

The W65C02 Microprocessor offers complete hardware and software capability with existing 6500 series products as well as significant enhancements. The W65C02 40-pin Dip plug compatible with the NMOS 6502 and acts as a direct replacement in existing systems. The W65C02 44-pin plastic chip carrier (PLCC) offers additional features such as Memory Lock Output (ML-) and Vector Pull (VP-).

In addition to compatibility, the CMOS Family offers many new features unavailable on NMOS products. These include higher reliability, greatly reduced power consumption, increased noise immunity, and other operational enhancements. In addition, ten new instructions (twenty-nine new opcodes) and two new addressing modes have been added. Also the W65C02 is able to run at higher clock speeds than the previous NMOS design.

Because of the popularity of the 6502 instruction set and the extended features listed here, the W65C02 is ideal for new application-specific designs. Also, the small die size makes the W65C02 an excellent choice as a core microprocessor in single-chip microcomputers.

The W65C02 instruction set is downward compatible with the W65C816/802 16-bit Microprocessor Family and with the forth-coming W65C832 32-bit Microprocessor Family.

KEY FEATURES OF THE W65C02

- * Advanced CMOS family that is compatible with NMOS 6500 series microprocessors
- * Uses single 1.2-6 volt power supply, 5 volts specified
- * Low power consumption (2mA @1 MHz) allows battery-powered operation, 10uA standby current
- * Enhanced instruction set:
 - 20 additional op codes encompassing ten new instructions enhance software performance compared to existing NMOS 6500 microprocessor instruction set
 - 66 microprocessor instructions
 - 180 operational codes
 - 15 addressing modes
- * 65K-byte addressable memory
- * 2,4,6,8 or 10MHz operation, timing compatible with W65C816/802
- * New Stop-The-Clock (STP) instruction compatible with W65C816/802
- * On-board clock generator/oscillator can be driven by an external single-phase clock input, an RC network, or a crystal circuit
- * Early address valid allows use with slower memories
- * Early write data for dynamic memories
- * 8-bit parallel processing
- * Decimal and binary arithmetic
- * Pipeline architecture
- * Programmable stack pointer
- * Variable length stack
- * Interrupt capability
- * Non-maskable interrupt
- * 8-bit bidirectional data bus
- * "Ready" input (for single cycle execution)
- * Direct memory access capability
- * New Wait-For-Interrupt (WAI) instruction compatible with W65C816/802

SECTION 1

W65C02 FUNCTIONAL DESCRIPTION

1.1 Instruction Register and Decode

Instructions fetched from memory are gated onto the internal data bus. These instructions are latched into the instruction register then decoded, along with timing and interrupt signals, to generate control signals for the various registers.

1.2 Timing Control Unit

The Timing Control Unit keeps track of the instruction cycle being monitored. The unit is set to zero each time an instruction fetch is executed and is advanced at the beginning of each PHI1 clock pulse for as many cycles as is required to complete the instruction. Each data transfer between registers depends upon decoding the contents of both the Instruction Register and the Timing Control Unit.

1.3 Arithmetic and Logic Unit

All arithmetic and logic operations take place within the ALU including incrementing and decrementing internal registers (except the program counter). The ALU has no internal memory and is used only to perform logical and transient numerical operations.

1.4 Accumulator

The Accumulator is a general purpose 8-bit register which stores the results of most arithmetic and logic operations. In addition, the accumulator usually contains one of the two data words used in these operations.

1.5 Index Registers

There are two 8-bit Index Registers (X and Y) which may be used to count program steps or to provide an index value to be used in generating an effective address. When executing an instruction which specifies indexed addressing, the CPU fetches the opcode and the base address, and modifies the address by adding the index register to it prior to performing the desired operation. Pre- or post-indexing of indirect addresses is possible.

1.6 Processor Status Register

The 8-bit Processor Status Register contains seven status flags. Some of the flags are controlled by the program, others may be controlled both by the program and the CPU. The 6500 instruction set contains a number of conditional branch instructions which are designed to allow testing of these flags.

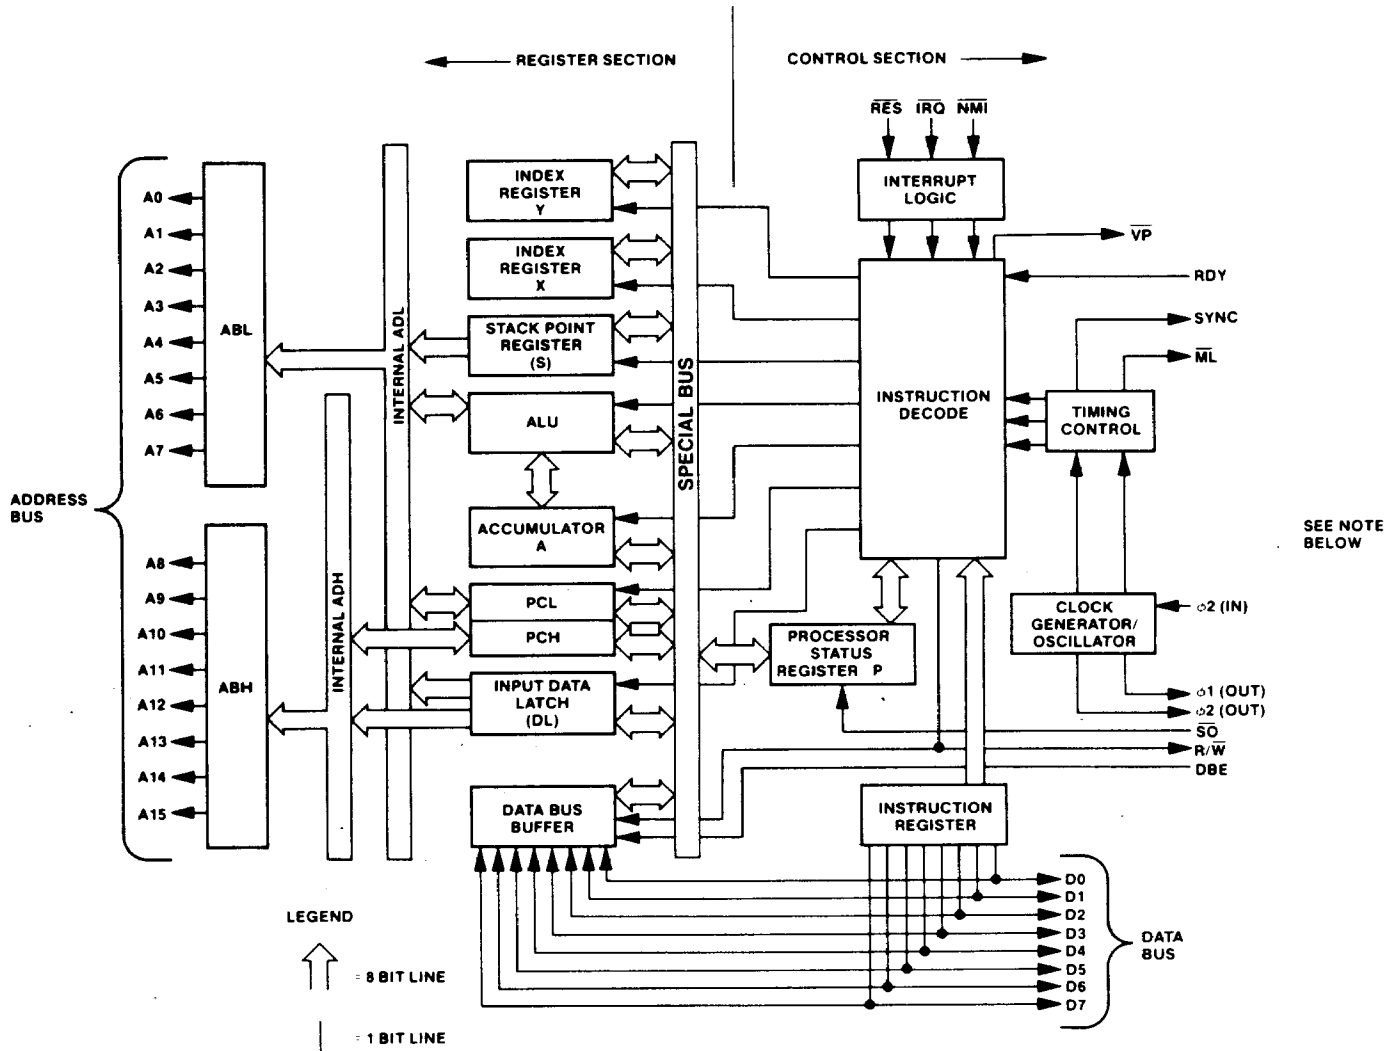

1.7 Program Counter

The 16-bit Program Counter Register provides the addresses which step the microprocessor through sequential program instructions. Each time the microprocessor fetches an instruction from program memory, the lower byte of the program counter (PCL) is placed on the low-order bits of the address bus and the higher byte of the program counter (PCH) is placed on the high-order 8 bits. The counter is incremented each time an instruction or data is fetched from program memory.

1.8 Stack Pointer

The Stack Pointer is an 8-bit register which is used to control the addressing of the variable-length stack. The stack pointer is automatically incremented and decremented under control of the microprocessor to perform stack manipulations under direction of either the program or interrupts (NMI- and IRQ-). The stack allows simple implementation of nested subroutines and multiple level interrupts.

| VSS | Internal Logic Ground |

2.1 Address Bus (A0-A15)

The address bus consists of A0-A15 forming a 16-bit address bus for memory and I/O exchanges on the data bus. The output of each address line is TTL compatible, capable of driving one standard TTL load and 130pF.

2.2 Data Bus (D0-D7)

The data lines constitute an 8-bit bidirectional data bus for use during data exchanges between the microprocessor and peripherals. The outputs are three-state buffers capable of driving one TTL load and 130 pF.

2.3 Interrupt Request (IRQ-)

This TTL compatible signal requests that an interrupt sequence begin within the microprocessor. The IRQ- is sampled during PHI2 operation; if the interrupt flag in the processor status register is zero, the current instruction is completed and the interrupt sequence begins during PHI1. The program counter and processor status register are stored in the stack. The microprocessor will then set the interrupt mask flag high so that no further interrupts may occur. At the end of this cycle, the program counter low will be loaded from address FFFE, and program counter high from location FFFF, transferring program control to the memory vector located at these addresses. The RDY signal must be in the high state for an interrupt to be recognized. A 3K ohm external resistor should be used for proper wire-OR operation.

2.4 Memory Lock (ML-) - (44 PLCC only)

In a multiprocessor system, ML- indicates the need to defer the re-arbitration of the next bus cycle to ensure the integrity of read-modify-write instructions, ML goes low during ASL, DEC, INC, LSR, ROL, ROR, TRB, TSB memory referencing instructions. This signal is low for the modify and write cycles.

2.5 Non-Maskable Interrupt (NMI-)

A negative-going edge on this input requests that a non-maskable interrupt sequence be generated within the microprocessor. The NMI- is sampled during PHI2; the current instruction is completed and the interrupt sequence begins during PHI1. The program counter is loaded with the interrupt vector from locations FFFA (low byte) and FFFB (high byte), thereby transferring program control to the non-maskable interrupt routine. However, it should be noted this is an edge-sensitive input. As a result, another interrupt will occur if there is another negative-going transition and the program has not returned from a previous interrupt. Also, no interrupt will occur if NMI- is low and a negative-going edge has not occurred since the last non-maskable interrupt.

2.6 Phase 1 Out (PHI1(OUT))

Inverted PHI2(OUT) signal.

2.7 Phase 2 In (PHI2(IN))

This is the buffered clock input to the internal clock generator. The clock outputs, PHI1(OUT) and PHI2(OUT), are derived from this signal.

2.8 Phase 2 Out (PHI2(OUT))

This signal is generated from PHI2(IN). PHI2(IN) provides timing for the system.

2.9 Read/Write (R/W-)

This signal is normally in the high state indicating that the microprocessor is reading data from memory of I/O bus. In the low state the data bus has valid data from the microprocessor to be stored at the addressed memory location.

2.10 Ready (RDY)

This bidirectional signal allows the user to single-cycle the microprocessor on all cycles including write cycles. A negative transition to the low state during or coincident with PHI1 will halt the microprocessor with the output address lines reflecting the current address being fetched. This condition will remain through a subsequent phase two in which the ready signal is low. This feature allows microprocessor interfacing with low-speed memory as well as direct memory access (DMA). The new WAI instruction pulls RDY low signaling the Wait-For-Interrupt condition, thus RDY is a bidirectional pin.

2.11 Reset (RES-)

This input is used to reset the microprocessor. Reset must be held low for at least two clock cycles after VDD reaches operating voltage from a power down. A positive transition of this pin will then cause an initialization sequence to begin. After the system has been operating, a low on this line of at least two cycles will cease microprocessor activity. When a positive edge is detected, there is an initialization sequence lasting six clock cycles. Then the interrupt mask flag is set, the decimal mode is cleared and the program counter is loaded with the restart vector from locations FFEC (low byte) and FFED (high byte). This is the start location for program control this input should be high in normal operation.

2.12 Set Overflow (SO-)

A negative transition on this line sets the overflow bit in the status code register. The signal is sampled on the trailing edge of PHI1.

2.13 Synchronize (SYNC)

The SYNC output is provided to identify those cycles during which the microprocessor is fetching an opcode. The SYNC line goes high during PHI1 of an opcode fetch and stays high for the remainder of that cycle. If the RDY line is pulled low during the PHI1 clock pulse in which SYNC went high, the processor will stop in its current state and will remain in the state until the RDY line goes high. In this manner, the SYNC signal can be used to control RDY to cause single instruction execution.

2.14 VDD and VSS

VDD is the positive supply voltage and VSS is system logic ground.

2.15 Vector Pull (VP-) - (44 PLCC only)

The Vector Pull output indicates that a vector location is being addressed during an interrupt sequence. VP- is low during the last two interrupt sequence cycles, during which time the processor reads the interrupt vector. The VP- signal may be used to select and prioritize interrupts from several sources by modifying the vector addresses.

SECTION 3

ADDRESSING MODES

Fifteen addressing modes are available to the user of the WDC W65C02 microprocessor. The addressing modes are described in the following paragraphs:

3.1 Immediate Addressing

With immediate addressing, the operand is contained in the second byte of the instruction; no further memory addressing is required.

3.2 Absolute Addressing

For absolute addressing, the second byte of the instruction specifies the eight low order bits of the effective address while the third byte specifies the eight high order bits. Therefore, this addressing mode allows access to the total 65K bytes of addressable memory.

3.3 Zero Page Addressing

Zero page addressing allows shorter code and execution times by only fetching the second byte of the instruction and assuming a zero high address byte. The careful use of zero page addressing can result in significant increase in code efficiency.

3.4 Implied Addressing

In the implied addressing mode, the address containing the operand is implicitly stated in the operation code of the instruction.

3.5 Accumulator Addressing

This form of addressing is represented with a one byte instruction and implies an operation on the accumulator. The opcodes are included under implied addressing.

3.6 Zero Page Indexed Indirect Addressing: (IND,X)

With zero page indexed indirect addressing (usually referred to as Indirect X) the second byte of the instruction is added to the contents of the X index register; the carry is discarded. The result of this addition points to a memory location on page zero whose contents is the low order eight bits of the effective address. The next memory location in page zero contains the high order eight bits of the effective address. Both memory locations specifying the high and low order bytes of the effective address must in page zero.

3.7 Absolute Indexed Indirect Addressing (Jump Instruction only)

With absolute indexed indirect addressing, the contents of the second and third instruction bytes are added to the X register. The result of this addition points to a memory location containing the lower order eight bits of the effective address. The next memory location contains the higher-order eight bits of the effective address (opcode 7C).

3.8 Indirect Indexed Addressing: (IND), Y

This form of addressing is usually referred to as Indirect, Y. The second byte of the instruction points to a memory location in page zero. The contents of this memory location is added to the contents of the Y index register, the result being the low order eight bits of the effective address. The carry from this addition is added to the contents of the next page zero memory location, the result being the high order eight bits of the effective address.

3.9 Zero Page Indexed Addressing

Zero page absolute addressing is used in conjunction with the index register and is referred to as "Zero Page, X" or "Zero Page, Y". The effective address is calculated by adding the second byte to the contents of the index register. Since this is a form of "Zero Page" addressing, the content of the second byte references a location in page zero. Additionally, due to the "Zero Page" addressing nature of this mode, no carry is added to the high order eight bits of memory and crossing of page boundaries does not occur.

3.10 Absolute Indexed Addressing

Absolute indexed addressing is used in conjunction with X and Y index register and is referred to as "Absolute, X", and "Absolute, Y". The effective address is formed by adding the contents of X and Y to the address contained in the second and third bytes of the instruction. This mode allows the index register to contain the index or count value and the instruction to contain the base address. This type of indexing allows any location referencing and the index to modify multiple fields resulting in reduced coding and execution time.

3.11 Relative Addressing

Relative addressing is used only with branch instruction, it established a destination for the conditional branch.

3.12 Zero Page Indirect Addressing: Indirect

In this form of addressing, the second byte of the instruction contains the low order eight bits of a memory location. The high order eight bits is always zero. The contents of the fully specified memory location is the low order byte of the effective address. The next memory location contains the high order byte of the effective address.

3.13 Absolute Indirect Addressing (Jump Instruction Only)

The second byte of the instruction contains the low order eight bits of memory location. The high order eight bits of that memory location is contained in the third byte of the instruction. The contents of the fully specified memory location is the low order byte of the effective address. The next memory location contains the high order byte of the effective address which is loaded into the 16 bits of the program counter (opcode 6C).

SECTION 4**TIMING, AC AND DC CHARACTERISTICS****4.1 Absolute Maximum Ratings****Table 4-1 Absolute Maximum Ratings**

| Rating | Symbol | Value |
|-----------------------|--------|-------------------|
| Supply Voltage | VDD | -0.3 to +7.0V |
| Input Voltage | VIN | -0.3 to VDD +0.3V |
| Operating Temperature | TA | 0 °C to +70°C |
| Storage Temperature | TS | -55 °C to +150°C |

This device contains input protection against damage due to high static voltages or electric fields; however, precautions should be taken to avoid application of voltages higher than the maximum rating.

Note:

Exceeding these ratings may result in permanent damage. Functional operation under these conditions is not implied.

4.2 DC Characteristics VDD = 5.0V +/- 5%, VSS = 0V, TA = 0°C to +70°C

WARNING:

MOS CIRCUITS ARE SUBJECT TO DAMAGE FROM STATIC DISCHARGE

Internal static discharge circuits are provided to minimize part damage due to environmental static electrical charge build-ups. Industry established recommendations for handling MOS circuits include:

1. Ship and store product in conductive shipping tubes or conductive foam plastic. Never ship or store product in non-conductive plastic containers or non-conductive plastic foam material.
2. Handle MOS parts only at conductive work stations.
3. Ground all assembly and repair tools.

SECTION 6

APPLICATION INFORMATION

Table 6-1 W65C02 Instruction Set-Alphabetical Sequence

| | |
|--|--|
| ADC-Add Memory to Accumulator with Carry | NOP-No Operation |
| AND-"AND" Memory with Accumulator | * ORA-"OR" Memory with Accumulator |
| ASL-Shift One Bit Left | PHA-Push Accumulator on Stack |
| BCC-Branch on Carry Clear | PHP-Push Processor Status on Stack |
| BCS-Branch on Carry Set | # PHX-Push Index X on Stack |
| BEQ-Branch on Result Zero | # PHY-Push Index Y on Stack |
| * BIT-Test Memory Bits w/Accumulator | PLA-Pull Accumulator from Stack |
| | PLP-Pull Processor Status from Stack |
| BMI-Branch on Result Minus | # PLX-Pull Index X from Stack |
| BNE-Branch on Result Not Zero | # PLY-Pull Index Y from Stack |
| BPL-Branch on Result Plus | ROL-Rotate One Bit Left |
| # BRA-Branch Always | ROR-Rotate One Bit Right |
| BRK-Force Break | RTI-Return from Interrupt |
| BVC-Branch on Overflow Clear | RTS-Return from Subroutine |
| BVS-Branch on Overflow Set | * SBC-Subtract Memory from Accumulator with Borrow |
| CLC-Clear Carry Flag | SEC-Set Carry Flag |
| CLD-Clear Decimal Mode | SED-Set Decimal Mode |
| CLI-Clear Interrupt Disable Bit | SEI-Set Interrupt Disable Bit |
| CLV-Clear Overflow Flag | * STA-Store Accumulator in Memory |
| * CMP-Compare Memory and Accumulator | # STP-Stop the Clock |
| CPX-Compare Memory and Index X | STX-Store Index X in Memory |
| CPY-Compare Memory and Index Y | STY-Store Index Y in Memory |
| * DEC-Decrement by One | # STZ-Store Zero in Memory |
| DEX-Decrement Index X by One | TAX-Transfer Accumulator to Index X |
| DEY-Decrement Index Y by One | TAY-Transfer Accumulator to Index Y |
| * EOR-"Exclusive-or" Memory with Accumulator | # TRB-Test and Reset Memory Bits with Accumulator |
| * INC-Increment by One | # TSB-Test and Set Memory Bits with Accumulator |
| INX-Increment Index X by One | TSC-Transfer Stack Pointer Register to Accumulator |
| INY-Increment Index Y by One | TSX-Transfer Stack Pointer to Index X |
| * JMP-Jump to New Location | TXA-Transfer Index X to Accumulator |
| JSR-Jump to New Location Saving Return Address | TXS-Transfer Index X to Stack Pointer |
| * LDA-Load Accumulator with Memory | TYA-Transfer Index Y to Accumulator |
| LDX-Load Index X with Memory | # WAI-Wait for Interrupt |
| LDY-Load Index Y with Memory | |
| LSR-Shift One Bit Right | |
| # - New instruction | |
| * - Old instruction with New Addressing Modes | |

Table 6-2 Vector Locations

FFFE, F-IRQ-/BRK Hardware/Software
 FFFC, D-RESET- Hardware
 FFFA, B-NMI- Hardware

The VP output is low during the two cycles used for vector location access. When an interrupt is executed, D=0 and I=1 in Status Register P.

Table 6-3 Opcode Matrix

| MSD \ LSD | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | A | B | C | D | E | F | |

Notes: 1. Add 1 to "n" if page boundary is crossed, except STA and STZ

2. Add 1 to "n" if branch occurs to same page. Add 2 to "n" if branch occurs to different page.

2. Add 1 to "n" if branch occurs.
3. Add 1 to "n" if decimal mode.

4. Accumulator address is included in Implied address

4. Accumulator address is increased in indirect addressing
5. "N" and "V" flags are unchanged in immediate mode

6 "Z" flag indicates AAM result (same as BIT instruction)

X Index X

Y Index Y

A Accumulator

M Memory per effective address

Ms Memory per stack pointer

+ Add

- Subtract

Λ And M₆ Memory Bit #6

V Or M: Memory Bit #7

✚ Exclusive or

Table 6-5 Instruction Operation (13)

| ADDRESS MODE | CYCLE | (14) \overline{VP} | (14) \overline{ML} | (14) \overline{VDA} | (15) \overline{VPA} | ADDRESS BUS | DATA BUS | R/ \overline{W} |
|--|---------|----------------------|----------------------|-----------------------|-----------------------|-------------|------------|-------------------|
| 1. Immediate-# (LDY, CPY, CPX, LDX, ORA, AND, EOR, ADC, BIT, LDA, (1) CMP, SBC, REP, SEP) (14 OpCodes) (2 and 3 bytes) (2 and 3 cycles) | 1. | 1 | 1 | 1 | 1 | PBR, PC | OpCode | 1 |
| | 2. | 1 | 1 | 0 | 1 | PBR, PC+1 | IDL | 1 |
| | (1) 2a. | 1 | 1 | 0 | 1 | PBR, PC+2 | IDH | 1 |

Notes: Be aware that notes #4-7, 9 and 10 apply to the W65C02 and W65C816.
All other notes apply to the W65C816 only.

1. Add 1 byte (for immediate only) for M=0 or X=0 (i.e. 16-bit data), add 1 cycle for M=0 or X=0.
2. Add 1 cycle for direct register low (DL) not equal 0.
3. Special case for aborting instruction. This is the last cycle which may be aborted or the Status, PBR or DBR registers will be updated.
4. Add 1 cycle for indexing across page boundaries, or write, or X=0. When X=1 or in the emulation mode, this cycle contains invalid addresses.
5. Add 1 cycle if branch is taken.
6. Add 1 cycle if branch is taken across page boundaries in 6502 emulation mode (E=1).
7. Subtract 1 cycle for 6502 emulation mode (E=1).
8. Add 1 cycle for REP, SEP.
9. Wait at cycle 2 for 2 cycles after NMI- or IRQ- active input.
10. R/W- remains high during Reset.
11. BRK bit 4 equals "0" in Emulation mode.
12. PHP and PLP.
13. Some OpCodes shown are compatible only with the W65C816.
14. VDA and VPA are not valid outputs on the W65C02 but are valid on the W65C816. The two signals, VDA and VPA, are included to point out the upward compatibility to the W65C816. When VDA and VPA are both a one level, this is equivalent to SYNC being a one level.
15. The PBR is only applicable to the W65C816.
16. COP Latches.

SECTION 7

CAVEATS

Table 7-1 Microprocessor Operational Enhancements

| Function | NMOS 6502 | W65C02 |
|---|---|--|
| Indexed addressing across page boundary. | Extra read of invalid address. | Extra read of last instruction byte. |
| Execution of invalid opcodes. | Some terminate only by reset. Results are undefined | All are NOP's (reserved for future use). Op Code Bytes Cycles X2 2 2 X3, X7, 0B-BB, 1 1 EB, FB 44 2 3 54, D4, F4 2 4 5C 3 8 DC, FC 3 4 |
| Jump indirect, operand = XXFF. | Page address does not increment. | Page address increments, one additional cycle. |
| Read/modify/write instruction at effective address. | One read and two write cycles. | Two read and one write cycle. |
| Decimal flag. | Indeterminate after reset. | Initialized to binary mode (D=0) after reset and interrupts. |
| Flags after decimal operation. | Invalid N, V and Z flags. | Valid flags. One additional cycle. |
| Interrupt after fetch of BRK instruction. | Interrupt vector is loaded; BRK vector is ignored. | BRK is executed, then interrupt is executed. |
| Ready. | Input. | Bidirectional, WAI instruction pulls low. |
| Read/modify/write instructions absolute indexed in same page. | Seven cycles. | Six cycles. |

Table 7-2 Microprocessor Hardware Enhancements

| Function | NMOS 6502 | W65C02 |
|---|--|---|
| Oscillator. | Requires external active components. | Crystal or RC network will oscillate when connected between PHI2(IN) and PHI1(OUT). |
| Assertion of Ready (RDY) during write operations. | Ignored. | Stops processor during PHI2, and bidirectional WAI instruction pulls RDY low. |
| Clock inputs. | Two non-overlapping clock inputs (PHI1 and PHI2) are required. | PHI2(IN) is the only required clock. |
| Unused input-only pins | Must be connected to low impedance signal to avoid noise problems. | Connected internally by a high-resistance to VDD (approximately 1 Megohm). |

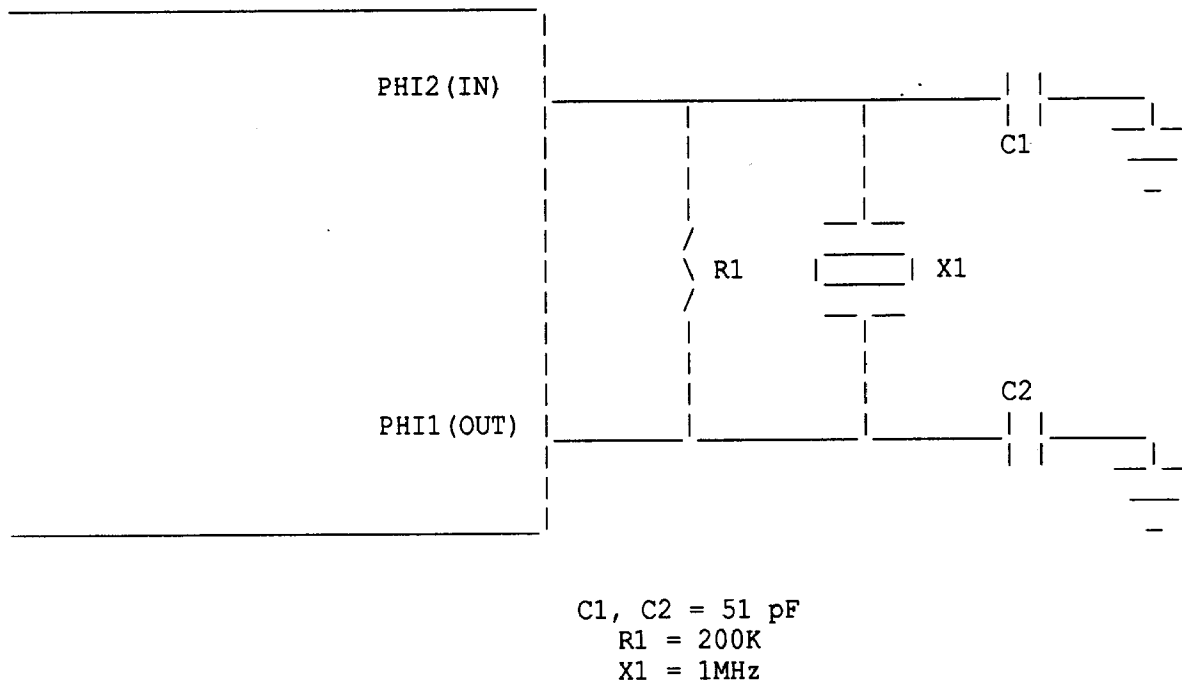

Figure 7-1 Crystal Circuit for Internal Oscillator

SECTION 8

TOOLBOX DESIGN SYSTEM

In-Circuit Emulator for the W65C02, W65C816, W65C134 and W65C265

8.1 Features

- * Hardware Breakpoint on any combination of address, data, read/write, instruction fetch, and user-defined I/O
- * Instruction single-stepping and single cycle capability
- * Target memory display and editor
- * Microprocessor register display and editor
- * 2048-cycle real-time trace buffer providing logic analyzer-type features
- * W65C816/W65C02 cycle disassembler
- * Can ICE targets with clock rates from 32 KHz to 4 Mhz
- * Ability to save and load target memory to/from disk files
- * 64K RAM/ROM overlay in target system address space
- * C-language based ICE software

8.2 Product Overview

The Toolbox Design System In-Circuit Emulator (ICE) is a hardware/software debugger for WDC's W65C series of microprocessors and microcontrollers. These include the W65C02, W65C816, W65C134 (C02 core) and the W65C265 (816 core).

An Apple IIgs acts as a host system. An interface card connected to the Toolbox plugs into one of the Apple IIgs expansion slots. ICE Software running on the host is used to control the Toolbox and to control ICEing.

To "ICE" a system, a cable from the Toolbox plugs into the target system microprocessor socket. From the host system, the user can single step the microprocessor or run at the normal clock rate. When running at the normal clock rate, the Toolbox is "transparent" to the target system.
